## WHAT IS IT?

A gaming computer is a desktop computer that is often custom built for the purpose of increasing performance in modern computer games. It may require an increase amount of power due to the graphics and processing. One of the most significant differences between regular and gaming machines is the video processing.

The difference a gaming PC typically has is a more powerful CPU and video card plus (usually) more RAM and storage space than a general purpose computer because games tend to be very demanding of hardware resources (downloads). Think of a gaming computer as a Porsche, and a regular computer as a Chevy.
